2014 AMS Annual Meeting in Atlanta, GA, February 2-6

transitioning unique NASA data and research technologies to operations

Background

- Natural hazards become disasters when they affect life or property.
- Many natural disasters are meteorological in nature, or influenced by ongoing weather:
 - Tornadoes, hurricanes, typhoons, wildfires (lightning-initiated), drought, floods, blizzards, extreme temperature, and impacts on other human-caused disasters.
- Near real-time remote sensing offers several capabilities to support disaster assessment and response.
 - In addition, the broader availability of near real time Earth remote sensing provides continuity of weather observations to support response activities.

transitioning unique NASA data and research technologies to operations

The SPoRT Disasters Team

- SPoRT has a 10+ year relationship supporting NOAA's National Weather Service, providing new satellite products, analysis techniques, appropriate training, and collaborative partnerships.
- SPoRT provided imagery to NWS offices following the April 27, 2011 "Super Outbreak" of tornadoes across the southeastern U.S.
 - ROSES 2011: Applied Sciences: Disasters "feasibility study" award
- Primary goals of the feasibility study:
 - Include near real-time Earth remote sensing within the NWS "Damage Assessment Toolkit", the smartphone app used in the tornado damage survey process.
 - Demonstrate that satellite data adds value to the survey process.
 - Explore additional techniques for supporting disaster response and assessment via use of near real-time NASA, NOAA, and other data.
- SPoRT has provided imagery in support of Superstorm Sandy assessments, Super Typhoon Haiyan, and other events.

transitioning unique NASA data and research technologies to operations

Case Study: April 27, 2011

- We examined all Alabama tornadoes from April 27, 2011 and track detection from MODIS, Landsat-7, or ASTER.
 - Bell et al. (in review)
- Most tornadoes typically causing disasters (EF-2+) produce tracks visible in NDVI imagery during the primary severe weather season (March-August).

Case Study: April 27, 2011

In this example, the EF-3 tornado damage track is readily apparent.

An EF-1 track was also surveyed and is apparent from visual inspection, however, the ground survey limited the track extent. It may have been extended if satellite imagery were available.

Enabling Data Access Integration into the Damage Assessment Toolkit

The screenshot shows a mobile application interface for damage assessment. The top status bar indicates Verizon service, 11:05 AM, and 74% battery. The app header includes 'Back', 'SVR/TOR', 'GPS', and 'Menu' buttons. The left sidebar contains a 'Take Picture' button and a form for event details: Event ID, Storm Date (4/27/2011), DI (Small Barns or Farm Outbuildings (SBO)), DoD (Threshold of visible damage), Windspeed (62 mph), EF Rating (EF0), Direction (N/A), Injuries (0), Deaths (0), and a Comments field. The main map area displays an ASTER False Color Composite with labels for 'Phil Campbell-Huntsville Track' and 'Haleyville Track'. A vertical scale bar is on the left of the map. The right sidebar has buttons for 'Damage Layers', 'Basemaps', 'HiRes Imagery', and 'New Survey'. The bottom status bar shows 'Status: Online [TEST]' and 'Cache: (0)'. The text 'ASTER False Color Composite' and 'esri' logo are visible at the bottom of the map area.

Significant Events in 2013

- The feasibility study resulted in an evaluation version of the DAT application, suitable for testing the integration of satellite data sets.
- The SPoRT Disasters Team has examined use of NRT data within the DAT for:
 - The May 20, 2013 EF-5 tornado in Moore, OK
 - The November 17, 2013 EF-4 tornado in Washington, IL

Early Praise for NASA/NOAA Collaborations

“Using this (high resolution) imagery, we can revolutionize the way we conduct surveys ... If we had this imagery much sooner (**even within a month**), there's no telling how dead-on we could be with our surveys...and there would be little to no mistaking what actually happened (tornado vs. straight line winds).”

-- NWS Collaborator, Nashville, TN

“[The proposal team] got us images for the Moore, OK Tornado and the [Norman NWS] ... working with Parks Camp (proposal collaborator, NWS Tallahassee) and NASA ... re-defined the polygon as we were able to make the images available in Damage Assessment Toolkit. The imagery is very useful and has come in very handy for these types of events. Fortunately these also worked for the River Flooding in NWS Central Region's area. ***I think we should support this and the images have already been used in operations.***”

-- NWS Collaborator, NWS Southern Region HQ

transitioning unique NASA data and research technologies to operations

Summary and Future Work

- The SPoRT Disasters Team has successfully performed a feasibility study demonstrating integration of NRT Earth remote sensing within the NWS Damage Assessment Toolkit
 - Demonstrated benefits from April 27, 2011 case study in addition to high impact events of 2013.
 - Significant, early praise and excitement already received from NOAA/NWS partners.
- The team plans to continue supporting NOAA/NWS partners as part of a three-year Applied Sciences: Decisions award, if received in FY2014.
